ABSTRACT

A discussion of the teaching content or the educational material is always essential for both tutors and students in the teaching activities. In traditional way, a discussion can only be performed normally after courses also requires the absence of the students as well as the tutors.

The traditional approach of discussing shows its limitations. Inefficiency in knowledge acquisition: not all the students have the same question and the tutor is able to offer explanation for only one question at same time; time-consumption: ; low interactivity:

Thus, a discuss system with intense interactivity as well as in crowdsourcing way is highly needed. To achieve high interactivity, a discuss system with graphical tool and real-time data communication is proposed. Students are able to contribute their questions and answers to get to the bottom of his deficiencies of teaching content and the educational material. And students who has the same questions can instantly acquire the best solution which is recommended and approved by the community.

In order to validate and evaluate the concepts of this approach, an implementation of the proposed solution is developed on top of modern web technologies. Moreover, a usability questionnaire survey is proposed and delivered for a quantized evaluation of the client application. The performance of this application is also evaluated at the same time through the created simulation scenarios.

3 STATE OF THE ART

The following chapter gives an overview of state of the art. To achieve the high interactivity and responsiveness in the graphical discussion system, a lot of modern web technologies should be applied.

However, there are always plenty of alternatives for each technology which could differ from system to system. So it is important to investigate and analyse the existing solutions and capture an overview about different alternatives of technologies. It's also vital to understand the benefit and drawback of the technologies used. In addition, a

First of all, the general modern web technology and development workflow will be introduced, which goes through our whole development and has a great impact on the development efficiency. The next part describes the different graphical technologies on web, and which fits our system best. Then an overview of the real time communication technologies is illustrated and evaluated. At last, a collection of modern technologies applied within the backend server is listed.

3.1 MODERN WEB DEVELOPMENT

3.1.1 EVOLUTION

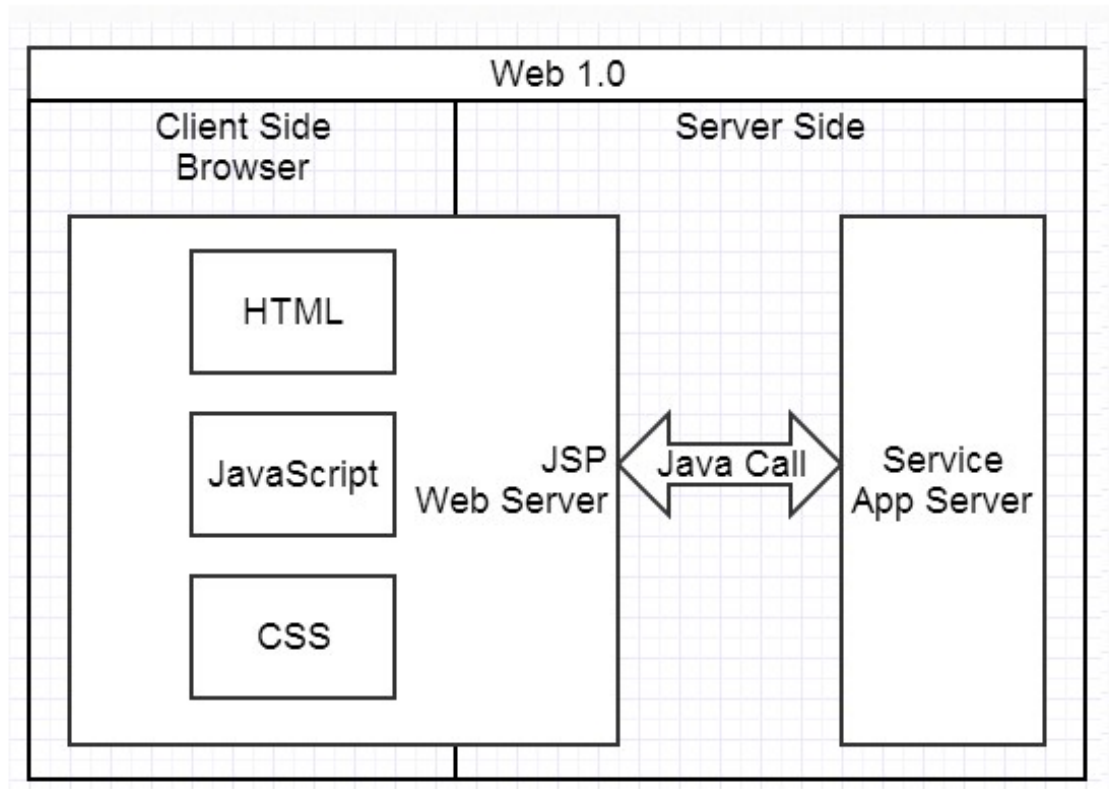

With the increasing complexity of a web app and high demand of agile development, people are always thinking about how to improve patterns of the workflow in web development as well as the architecture of a web app. To achieve better scalability, maintainability and ubiquity of a web app, the architecture of an entire web app has been evolving in the past several years .

EARLY AGE

At the early age of web development, the backend did all jobs for both client side(browser) and server side, such as rendering, calling system service, composing data, etc. Figure 3.1 shows the overview of web architecture: The advantage of this pattern is clear: The development and deployment are simple and straightforward, if the bussiness logic doesn't become complexer. But with the increasing complexity of the product, the problems shows up:

1. Development of frontend heavily depends on the whole development environment. Developers have to start up all the tools and services for testing and debugging only some small changes on view. In most cases, the frontend developer who isn't familiar with the backend needs help while intergrating the new views into the system. Not

Figure 3.1: Web architecture in early age

only the efficiency of development, but also the cost of communication between frontend developer and backend developer are huge problems.

2. The own responsibility of front-end and back-end mess up, which could be expressed by the commingled codes from different layers, for example there is no clear boundry from data processing tp data representing. The maintainability of the project becomes worse and worse with the increasing complexity.

It's really significant to improve the maintainability of code, as well as the efficiency and resrationality of division of work from both front-end and back-end in the whole web development phase. In the section below, a evolution of the technical architecture will reveal how these problems are solved.

WEB 2.0

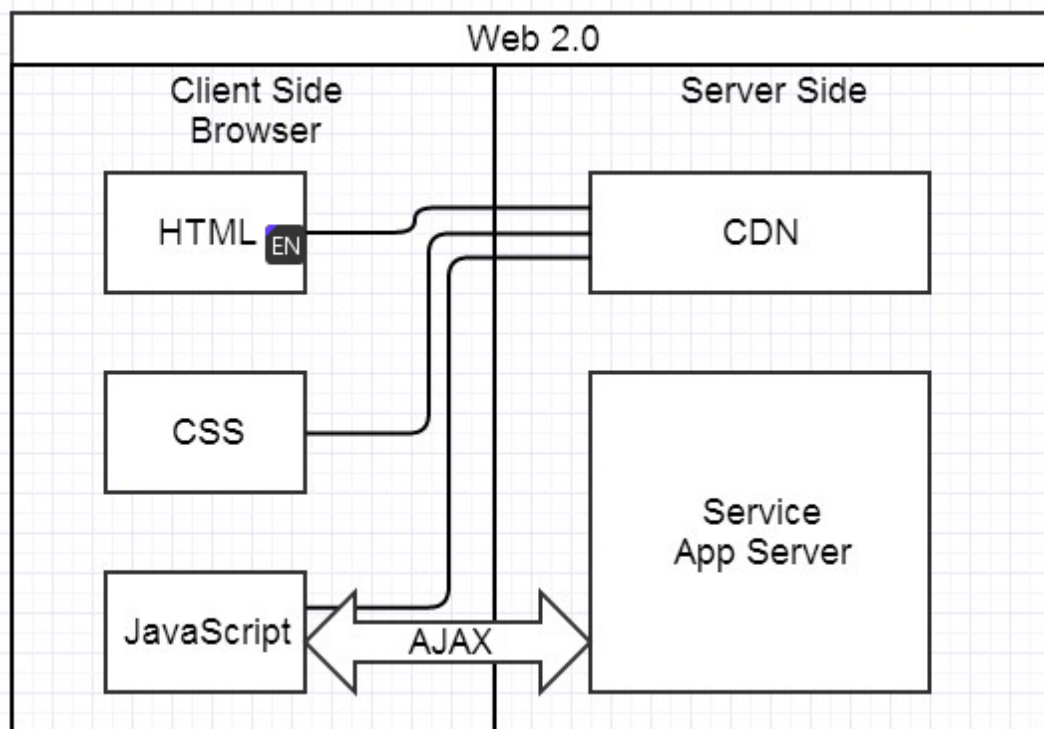

Along with the birth of Gmail¹ in 2004, which is noted for its pioneering use of Ajax, the web application started to behave more interactively. Browser began to take over the job of data fetching, processing, rendering, such a sequence of workflow which could only be done by the server side formerly.

The architecture in Web 2.0 generation is presented in figure 3.2.

By using Ajax, the client has the ability to fetching data stream asynchronously, after which the client will consume the data and render it into the specific section of view. Usability was dramatically improved, because the entired view represented to users will

¹<https://mail.google.com/>

Figure 3.2: Web 2.0 architecture

not be refreshed and the front-end is able to process and render data in its own intension, which means more flexible control of the consumption of data.

SINGLE PAGE APP

With the evolution of web technologies and promotion of these technologies in modern browsers by browser vendors, a new web development model called SPA was proposed and caught the developers' eye. The back-end is no more responsible for rendering and view controlling, it only take charge of providing services for the front-end.

The structure in figure 3.3 shows that the client side has the full control of view rendering and data consumption after data acquisition through web services which is released by back-end with promised protocol. All rendering tasks was stripped off from the server side, which means that the server side achieves more efficiency and concentrate more on the core bussiness logics.

But more responsibility in front-end means more complexity. How to reduce the complexity and increace the maintainability of a front-end project becomes a significant problem. Developers come up with an new envolved variant of SPA as demonstrated in figure 3.4.

In general, the architecture is componentized and layered into template, controller and model. Each component is isolated and has its own view as well as correlated logics. Front-end frameworks like EmberJS, AngularJS, ReactJS are providing such a approach and development pattern for developers to build modern web apps. With this approach, a giant and complex front-end app is broken up into fine grained components, therefore, components are easy to reuse if the components are well abstrated in a proper way. In addition, the maintainece of each component is also effortless.

Figure 3.3: SPA architecture

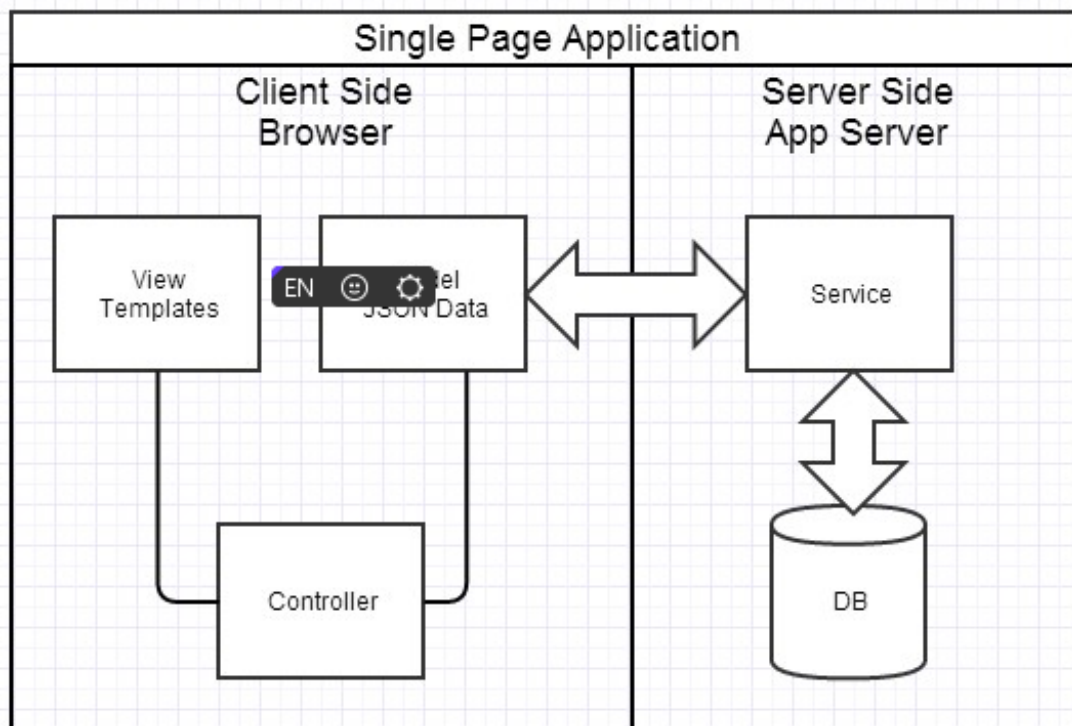

Figure 3.4: Components in SPA

TRADE-OFF

In summarize, a single-page app has a lot of benefits:

1. **Rational seperation of works from front-end and back-end:** client takes charge of view rendering and data representation, as well as slight data processing if needed; the server focus on providing services of the core logics, persistance of data, and also computational tasks.
2. **High interactivity and user experience in client side:** asynchronous data fetching and view rendering implies no more need of hard reloading the page which user is viewing and the current states of the page could also be preserved.
3. **Efficiency in server side:** rendering tasks are stripped off from server side.
4. **Ubiquity:** with the seperation of services provided by server side, not only the web browser but also other clients in other platforms such as Android, iOS apps are able to access and comsume the services.

But SPA also has its deficiencies:

1. **SEO unfriendly:** because the page are not directly rendered by server side, and the web crawlers are not able to run JavaScript codes like a browser does, the site could not be crawled properly under normal circumstances. So if SEO results really matter for the app, SPA is obviously not the best choice.
2. **Excessive http connections:** all the data is acquired from different services through diversified APIs, thus multiple HTTP connections are established and performed parallely, whose initial time of connections for partial data could be much more than a single connection in the traditional way. So it's highly needed to merge the services and find a balance between data model complexity and time consumption.

3.1.2 RESTFUL INTERFACE

3.1.3 CONTINUOUS INTEGRATION

3.1.4 OPERATING-SYSTEM-LEVEL VIRTUALIZATION

3.5 EFFICIENT SERVER SIDE

3.6 CONCLUSION

TBD

4 CONCEPTION

!!! In this chapter a conception of the discuss system including both client and server side will be described. In the first section, all the essential requirements are presented. After that, the general conception or workflow of the application will be proposed. The more concrete details and definitions of the conception will also be outlined. In addition, the focal points behind the conception and the proper solutions of the difficulties will be illustrated.

4.1 AIMS AND OBJECTIVES

Before starting to concept the graphical discuss system, it's necessary to analyse requirements and objectives behind the origin motivation in the first place. It should be defined at first, what kind of functionalities should be achieved and how the system behaves.

4.1.1 BASIC FUNCTIONALITIES

As a graphical discuss system for the educational purpose, the system should contain basic functionalities on the prototype of a forum which could be organized by classes. So class management, question management and answer management are the three essential parameters to be designed at the start.

COURSE MANAGEMENT

Each question should have a certain domain of its content, so the questions are organized by classes initially. The features of course management should be:

1. **Create Course:** The user who is identified as a tutor is able to create course and maintain the course he created. While creating the course, the tutor can define the name of the course and upload an image as a background of the course for better recognition. In addition, concret description of the course could also be added to the description area.
2. **Search Course:** After a course is created, a corresponding unique identifier code for the course will be generated at the same time. The students are able to find the course through the identifier code.
3. **Favor Course:** If a student is interest to a certain course, he is capable to add the course to his favor list so that it's easy to find and access the course he liked later.

Figure 4.1: placeholder

Figure 4.2: placeholder

Figure 4.3: placeholder

QUESTION MANAGEMENT

1. **Submit/Edit/Withdraw Question:** The student who has confusion with the teaching content can submit his own question with detailed description in a certain course. The user is also permitted to edit the question if he want to add more precise informations or modify the unclarity he made to the question. Withdrawing of his own question is also possible, but only when there're no contributes made to the question.

Figure 4.4: placeholder

2. **Upvote/Downvote Question:** An assessment of a question is decisive for building a better community with high-quality contents. So the user is able to upvote or downvote of a question and determine if the question is helpful for other members in the community or not.

Figure 4.5: placeholder

3. **Favor Question:** If the student consider the question as a helpful and useful content and want to review this question in the future, he can favor the question and locate it in a certain list.
4. **Accept Answer:** The owner of the question has the right to accept the most useful answer in his opion which will be shown up at the top of the answer list.

Figure 4.6: placeholder

Figure 4.7: placeholder

ANSWER MANAGEMENT

1. **Submit/Modify/Remove Answer:** User who has experience with the question can submit his answer to the question. After the submission, the modification or removal of the user's own question is possible.

Figure 4.8: placeholder

2. **Upvote/Downvote Answer:** As mentioned above in section of question functionality, a similar idea of assessment should also be applied to answers. Answer with higher vote will be listed at first.

Figure 4.9: placeholder

3. **Quote Answer:** Answers are able to be quoted so that the user can supplement informations on the top of original post or point out the deficiency of the contribute.

4.1.2 HIGH INTERATIVITY

Building with the basic functionalities is far not enough. To fit the system for educational purpose and improve the interactivity for arousing enthusiasm of students, a drawing tool and realtime functionality should be intergrated into the system.

Figure 4.10: placeholder

DRAWING TOOL

Normally, some of the thoughts can't be simply expressed by textual description, so a drawing tool should be designed to enable the user to compose not only text but also different components such like rectangle, circle, line and so on, which helps the user to express his question more precisely. The ideal drawing tool should have following features:

1. **Drawing Diverse Components:** Not only text but also diverse components could be drawn while posting a contribution. Styling of a component such as size tuning, color changing is also the essential, which will help emphasize the important part the user expressing.

Figure 4.11: placeholder

2. **Drawing History:** During drawing, the user might make mistakes or change mind after placing a component or text. So a history list of drawing actions bundled with undo and redo functionalities will dramatically improve the usability of drawing process.

Figure 4.12: placeholder

REALTIME

How to ease the approach of content acquisition and improve the interactivity for arousing enthusiasm of students, is also a key point while designing the discuss system. So two major realtime functionalities are featured as follow:

1. **Realtime Question List:** Without requesting the question list initiatively, all new questions posted by other users will be pushed to user automatically. The user doesn't have to concern himself with acquisition of the new content anymore.

Figure 4.13: placeholder

2. **Realtime Answer Ordering:** Without refreshing the page, the answers will be re-ordered as new vote action is triggered.

4.2 GENERAL CONCEPT

Before the whole conception of the system, a general conceptual architecture of the system should be defined initially. In order to help understanding how the system works, the primary data flow between different domains will also be described.

Figure 4.14: placeholder

4.2.1 ARCHITECTURE

According to the analysis result of Single-Page-App in chapter 3, and considering the demand on high interactivity and ubiquity as well as scalability in the graphical discuss system, leveraging SPA architecture will benefit a lot and accelerate the implementation of the system.

In general, the entire system will be divided into two parts: namely client and server-side. Each side is basically full independent to the other and has its own responsibility.

1. **Client:** The client is totally responsible for initial view rendering and view re-rendering as the view model changes.
2. **Server:** The server is in charge of core business logic, data processing, data persistence and also provides the client interfaces for data acquisition.

Figure 4.15: placeholder

General architecture of the system is described in figure 4.15, the only bridge between the client and server-side is data transmission service. Complete separation of both sides will also accelerate the development flow in implementation phase. Once the protocol of

data transmission services is fully confirmed and defined, development of each side is able to performed parallelly. Furthermore, technical choices on both sides are more flexible. Both sides are able to apply the technologies which fit them most without coupling to each other, the only thing they should obey is to follow the protocol of data transmission.

4.2.2 COMMUNICATION

As mentioned above in section 4.2.1, data communication is the only coupling factor in the general architecture. In this system, there exist two different type of protocols: standard HTTP using REST architecture and WebSocket with persistent connection. Each data transmission protocol has its own responsibility and usage scenario.

1. **HTTP with REST architecture:** Data which is requested initiatively is transferred over HTTP. The HTTP connection will be closed as soon as the data is successfully transferred.
2. **WebSocket with persistent connection:** Reactive data with realtime need is transferred over WebSocket. After the persistent connection is established, client are able to receive the data at the first moment as the state of data is updated.

Figure 4.16: placeholder

As figure 4.16 shows, in case data for view model is acquired from server despite transferred over HTTP or WebSocket, the views are re-rendered. Comparing with HTTP, the specialty of data acquisition over WebSocket is: a listener for specific resource with unified process of data processing and automatic view re-rendering will be created.

4.3 DATA

In this section, data modelling of the system including definitions of data domain, data fields for each domain, and relation between domains will be performed in the first place. In the following subsection, APIs corresponding to related operations on data models will be assigned.

4.3.1 GENERAL DATA MODEL

DATA DOMAIN

In general, data in the system could be divided into 4 primary domains:

1. **User:** personal information as well as user identifier for accessing the system.
2. **Course:** a container with own course information as well as collection of questions classified to this context.
3. **Question:** data with information of questions submitted by users.
4. **Answer:** data with information of answers, also has graphical data within the data model.

Users are able to assess the contributions made by other users and mark it as useful or useless, which will affect the contributions' order priority while rendering the views. Voters should also be aware of what kind of vote he has marked to the contribution. Therefore, additional 2 data models **VoteAnswer** and **VoteQuestion** should also be considered.

The relation between domains is illustrated in the following figure ???. Each data model has a unique identifier, which is referenced in another data model when they have a connection.

Figure 4.17: placeholder

DATA FIELDS

More detailed definition and description of fields in each data model should be made for a better understanding of the structure as well as behaviour of a data model. Tabel ?? describes key fields of general domains.

4.3.2 RESTFUL API DEFINITIONS

As mentioned in section xxx, RESTful architecture is an excellent technical choice for data transferring. Because of its simplicity and clear semantic description of HTTP methods comparing to other protocols such like SOAP, it will dramatically simplify and clarify our data transmission services.

Domain	Field	Description
User	email	unique identifier of an user for authentication, also as contact way to user.
	password	string for user authentication to prove identity or access approval
	username	user identifier shown to other users
	isTutor	flag which determines if the user is a student or tutor
Course	name	name of the course
	desc	description of the course
	creator	id of the user(tutor) who created this course
	code	unique code for quick search purpose which is generated automatically as the course is created
Question	title	title of the question
	content	content of the question
	course	id of the the course to which the question belongs
	vote	vote count of the question
Answer	creator	id of the user who submitted this question
	content	content of the answer
	question	id of the question for which the answer is made
	quoted	id of the original question which is quoted
Vote	vote	vote count of the answer
	creator	id of the submitter
	type	enum values of up-voting or down-voting actions
	handler	id of the handler
Vote	question/answer	id of the question/answer to which the vote action is applied

Table 4.1: Fields for Each Data Domain

MAPPING OF HTTP METHODS TO DATA MODEL BEHAVIOUR

The data model defined above can directly map to the definition of resources in RESTful. The HTTP methods on each resource domain can also represent the data model behaviours, *User Model* is taken as an example:

Method	Operation of data model collection
GET	Query and return a specific user from user model collection.
POST	Create a new user entry and insert into user model collection.
PUT	Update a specific user in user model collection.
DELETE	Delete a specific user in user model collection.

Table 4.2: HTTP methods on User resource

In table ??, resource entry in persistent storage can be executed with specific action while requesting resource URI through different HTTP methods. A semantic description of connection between CRUD and HTTP methods on RESTful will make the data transmission services more understandable and unified.

GENERAL RESTFUL API DEFINITIONS

Requesting a specific resource can only succeed through its URI, through which the client and server-side could connect to each other actually. Therefore, a definition of APIs which describes URI of the resources and its functional responsibility should be proposed in the first place.

1. **User Authentication:** the major actions of user authentication include signup, login, logout. To protect the user information, POST method which doesn't expose information via the URL, is highly recommended.

URI	Method	Description
/auth/login	POST	User login action, request with login information.
/auth/signup	POST	User signup action, request with registration information.
/auth/logout	GET	User logout action, no data submission is needed.

Table 4.3: User Auth APIs

2. **Courses:** acquisition of courses and new submission of a course is possible. In addition, CRUD operations on a specific course should also be achieved through a single URI with various HTTP methods.

URI	Method	Description
/courses	GET/POST	request the whole collection of courses; create course with data submitted
/courses/:courseId	GET/PUT/DELETE	request, modify, remove specific entry of course

Table 4.4: Course Resource APIs

3. **Questions:** in a real sense question resource is attached to course resource. According to the best practise of RESTful API design [reference xxx], question resource

could be touched under course URI, */courses/:courseId/questions/:questionId*. But in the real world, question resource has its own collection, and *questionId* is the unique identifier, through which a specific question entry could be selected without using *courseId*. So an optimized conception is simply using */questions* as URI instead. And pass *courseId* as a query parameter while requesting collection of question entries under a specific course.

URI	Method	Description
<i>/questions?courseId=:id</i>	GET/POST	request the whole collection of questions belonging to a specific course; create question under a specific course
<i>/questions/:id</i>	GET/PUT/DELETE	request, modify, remove specific entry of question
<i>/questions/:id/vote/:type</i>	POST	vote actions with different vote types applied to specific question

Table 4.5: Question Resource APIs

4. **Answers:** the general API design of answer is totally same as the approach applied in question resource. A independent API for voting functionality should also be designed. And multiple possibilities of vote types could also be passed through the API.

URI	Method	Description
<i>/answers?questionId=:id</i>	GET/POST	request the whole collection of answers belonging to a specific question; create answer under a specific question
<i>/answers/:id</i>	GET/PUT/DELETE	request, modify, remove specific entry of answer
<i>/answers/:id/vote/:type</i>	POST	vote actions with different vote types applied to specific answer

Table 4.6: Answer Resource APIs

Once all APIs with different HTTP methods are defined, a more concrete data structure over the APIs between two sides should be promised and confirmed. By following defined APIs and promised data structure, developments on both client and server-side could be executed parallelly.

4.3.3 WEBSOCKET DEFINITIONS

As the requirements defined in section 4.1, users could be informed as new question is posted or the order of answers with rating priority changes. Basically, only two different types of listeners are needed in this case: one for listening to the new questions under a specific class and one for responsive order of answers under a specific question. With WebSocket, URI should also be defined as an identifier for the persistent connection between client and server. And different events within a connection of one URI should also be designed. Table 4.7 defines these two WebSocket specifications.

URI	Event	Response
/ws/courses/	new-question	data of new question posted by others
/ws/questions/	order-changed	data of answers in new order

Table 4.7: Answer Resource APIs

4.4 GRAPHICAL DATA CONVERSION

Graphical content is the most efficient and intuitive way to deliver the explanation of an answer to other users comparing with pure textual content. In this section, Choices for graphical technologies on the Web will be analysed in order to figure out which is the ideal and fit the graphical discussion system most. And a feasible approach of storing graphical data will be proposed. At last, a drawing tool will also be designed to offer user interfaces for drawing elements on the drawing board.

4.4.1 CANVAS OVER SVG

It seems that both Canvas and SVG are good candidates as a graphic technology for the graphic discussion system. Both of them provides native methods to render rich varieties of elements like path, circle, rectangle and so on. Which would be a better choice above the context of discussion system, should be analysed at first.

EFFICIENCY

As mentioned in section 3.2, the rendering efficiency is the primary deficiency happening to SVG.

And graphic technologies are not only simply used for rendering a static graphical content in the system. Dragging, resizing or deleting an element are the basic features of a drawing tool, which provides input of graphical content. All these features are only able to be accomplished by re-rendering the elements on the drawing board.

Considering that all contributions in the system are made with graphical contents, efficiency plays a significant role especially on mobile devices with old hardware. Choosing Canvas will give users better usability while viewing the contributions as well as using the efficient drawing tool without janky feeling.

EXTENSIBILITY

TDB

4.4.2 STORABLE AND REVERSIBLE CANVAS DATA

A focus point in the thesis is how to store the graphical content submitted by users. In the traditional way, graphical data could only be stored either in file system or in the database with encoded format, for example Base64 encoded images.

DEFICIENCY OF CANVAS - STORABLE IMAGE DATA

Canvas provides a native method called *getImageData()* to export the whole Canvas context including the size of Canvas and pixels on Canvas to an image data. The image data exported by canvas represents the underlying pixel data with the format of *Uint8ClampedArray*.

The *Uint8ClampedArray* typed array represents an array of 8-bit unsigned integers clamped to 0-255 [reference], which implies the position of the pixel as the index of array and the color of pixel as value from 0 to 255. An example is taken in figure 4.18 shows a Canvas with content and its simplified ImageData.

Figure 4.18: placeholder

Restoring with the exported ImageData is also possible in Canvas by using its native method called *putImageData()*. Basically, the concept of *putImageData()* is traversing the ImageData exported by Canvas, and re-drawing each pixel at the position according to the index in the *Uint8ClampedArray* and applying the color to the pixel based on the value from 0 to 255 stored in the array.

Natively exported result of image data could basically meet the storing demand, however, the data redundancy in the native exported format representing the properties of each pixel is still very huge. Storing such kind of data will cause high demand on storage space when plenty of graphical contributions are made in there system.

Additionally, it is expected that users are able to remove, resize and modify the elements in the canvas while quoting others' contributions. However, natively exported result of image data could only describe each pixel but not each element on the Canvas, which means modification on the elements is not possible even though the whole canvas could be reproduced with graphical content by others.

Therefore, a workable solution should be conceptualized and new data model describing the graphical content in Canvas should be designed to meet the demands mentioned above.

SOLUTION - OBJECTIFICATION OF ELEMENTS IN CANVAS

Even though Canvas has native methods to draw different shapes of elements, but Canvas only render them pixel by pixel, it knows nothing of the shapes that are drawn. Therefore, removal or modification of a already drawn element is not possible. In this condition, a feasible solution is to wrap the Canvas and objectify the original elements which could be stored and persisted in a stack. Furthermore, the wrapper on Canvas should also provide methods to render, modify, remove the custom elements.

The general conception of the wrapped Canvas is illustrated in figure 4.19.

The wrapped Canvas has a list of objectified elements which are visible on Canvas. Now there are new definitions for rendering, modification of an objectified element:

1. **Rendering Canvas:** the list of elements maintained by wrapped Canvas will be traversed and each element will be rendered by calling the native drawing method of

Figure 4.19: placeholder

Canvas. Position and style of the element in Canvas refer to the properties of its object.

2. **Modification or Removal:** In case the methods for modifying or removing provided by element object in wrapped Canvas are fired, the whole Canvas will be re-rendered in the same way of rendering the Canvas initially.

Now rendering means that the list of elements maintained by wrapped canvas is traversed and each elements are

DATA MODEL EXPORTED BY WRAPPED CANVAS

Since the wrapped Canvas maintains a list of objects for elements, which also contain the properties such as position, color, size and so on, so the exporting of image data is now really simple. A composition of all objectified elements' properties is already enough to describe the whole canvas. Figure 4.20 reveals the approach and data model output from wrapped canvas.

Figure 4.20: placeholder

After converting all elements in wrapped canvas, the new data model is much more efficient for storing comparing to the raw image data. The wrapped Canvas will also provides a method to restore the output data, create new objectified elements by giving the properties of the data model, and re-render the elements into original Canvas pixel by pixel. With this approach, the feature of modification on elements while quoting other contributions could also be achieved.

4.4.3 DRAWING TOOL

After the conception of a feasible wrapped canvas as base of the container for all elements, a drawing tool which provides user interfaces to draw variable shapes as well as texts should be designed in the next step.

First of all, user interfaces for selecting different drawing mode like drawing circle, rectangle or line should be designed. Buttons for toggling various drawing modes are the best choice in this case.

Because drawing elements in different shapes has distinct behaviors, so listeners for each specific drawing mode should be defined. When the button for toggling drawing mode is clicked by user and specific drawing mode is activated, the correlative listener will be initiated. Clicking events or moving events of the mouse on Canvas will be captured and processed. Meanwhile, drawing behaviors are also performed according the mouse events fired by user.

Figure 4.21: placeholder

Figure 4.21 illustrated the conception of drawing tool with user interfaces and life cycle of event listeners for each drawing mode.

4.5 REAL-TIME DEMAND

Realtime communication as mentioned in subsection 4.2.2 are used for reactive data, which requires WebSocket for establishing persistent connections to enable the bi-directional communication between client and server.

All users are able to subscribe arbitrary course for new submission of a question as well as arbitrary question for updated order of answers, and server could also push realtime data to those users who has subscribed the resource with specific identifier. However, only two entry points for WebSocket services: */ws/courses* and */ws/questions* are defined according

to the definition in subsection 4.3.3. The approach how the server broadcast data precisely to the users who subscribe resources they require should be resolved.

A feasible solution is that the server maintains a list of user ids and resource ids subscribed by user. Afterwards, as a specific resource is updated, the server can get all users who has subscribed this resource from the maintained list using the resource's identifier.

Figure 4.22: placeholder

Figure 4.22 represents the whole workflow of establishing the connection over WebSocket. In the first place, the server start listening for requests in WebSocket protocol with specific URI. Then the user start a connection to server for subscribing the resource he requires. As soon as the connection is successfully established, the client will emit the resource id to the server side, and resource id from client will be mapped to the user id in a list maintained by the server.

After that, the server has the information of which user has subscribed which resource, and is able to emit realtime data precisely.
